Weight Updating

Learning in a "simple" perceptron vs a fully-connected network

(Lane et al., 2019, p. 158, 168)

¹Remember: aka linear regression

Backpropagation (of the errors)

- The error is computed on the output vector
- How much error did W_{1i} "contribute"?
- "Path": $W_{1i} \rightarrow [W_{1i}, W_{2i}] \rightarrow output$

Alberto Barrón-Cedeño (DIT-UniBO)

92586 Computational Linguistics

Backpropagation (of the errors)

A better activation function

Step function:
$$f(\vec{x}) = \begin{cases} 1 & \text{if } \sum_{i=0}^{n} x_i w_i > \text{threshold} \\ 0 & \text{otherwise} \end{cases}$$

Sigmoid function: non-linear and continuously differentiable

$$S(x) = \frac{1}{1 + e^{-x}} \tag{1}$$

Let us see

Non-linear \rightarrow model non-linear relationships

Continuously differentiable ightarrow partial derivatives wrt various variables to update the weights

Backpropagation

Differentiating to adjust

Squared error (in (Lane et al., 2019, p. 171) they say this is MSE; wrong)

$$SE = (y - f(x))^2 \tag{2}$$

Mean squared error

$$MSE = \frac{1}{n} \sum_{i=1}^{n} (y - f(x))^{2}$$
 (3)

Calculus chain rule

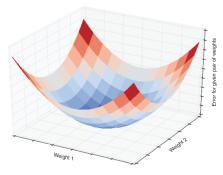

$$f(g(x))' = F'(x) = f'(g(x))g'(x)$$
(4)

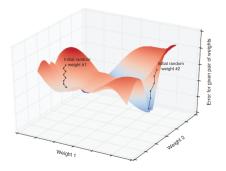

With (4) we can find the derivative of the actfunct \forall neuron wrt its input. Plain words: find the contribution of a weight to the error and adjust it! (no further math)

²Notice that the first W_{1i} should be W_{1i}

Backpropagation (of the errors)

~Gradient descent: minimising the error

Convex error curve

Non-convex error curve

(Lane et al., 2019, p. 173–174)

Alberto Barrón-Cedeño (DIT-UniBO)

Keras

16/04/2020

9 / 18

Addressing Local minima

Batch learning

- Aggregate the error for the batch
- Update the weight at the end
- ullet ightarrow hard to find global minimum

Stochastic gradient descent

- Look at the error for each single instance
- Update the weights right away
- ullet \to more likely to make it to the global minimum

Mini-batch

- Much smaller batch, combining the best of the two worlds
- ullet Fast as batch, resilient as stochastic gradient descent

Important parameter: learning rate α

A parameter to define at what extent should we "correct" the error

Alberto Barrón-Cedeño (DIT-UniBO)

Some Available Libraries

92586 Computational Linguistics

16/04/2020

10 / 18

There are many high- and low-level libraries in many languages

PyTorch

Community-driven; https://pytorch.org/

Theano

MILA (UdeM); www.deeplearning.net/software/theano/3

TensorFlow

Google Brain; https://www.tensorflow.org/

Others

We will use **Keras**; https://keras.io/

³Non active

Alberto Barrón-Cedeño (DIT-UniBO)

92586 Computational Linguistics

11 / 18

What is Keras

- High-level wrapper with an accessible API for Python
- Gives access to three alternative backends
 - ► Theano
 - ► ThensorFlow
 - ► CNTK (MS)

Alberto Barrón-Cedeño (DIT-UniBO)

Keras

Logical exclusive OR in Keras

input		output
0	0	0
0	1	1
1	0	1
1	1	0

Let us see

- First dense layer
 - ▶ 2 inputs, 10 neurons
 - ► 30 parameters
 - ▶ $2 \times 10 \rightarrow 20$
 - ▶ But we also have the bias! That's 10 more weights
- Second dense layer
 - ▶ 10 inputs, 1 neuron
 - ▶ 11 parameters

Now we can compile the model

■ Let us see

16/04/2020

"Design Decisions"

Activation functions

- Sigmoid
- RelU (rectified linear unit)
- tanh (hyperbolic tangent)

Learning rate

- Choosing one in advance
- Use alertmomentum to perform dynamic adjustments

Dropout

• Ignore randomly-chosen weights in a training pass to prevent overfitting

Regularisation

• Dampen a weight from growing/shrinking too far from the rest to prevent overfitting

Alberto Barrón-Cedeño (DIT-UniBO)

Normalisation

Example House classification.

Input number of bedrooms, last selling price

Output Likelihood of selling

Vector input_vec = [2, 90000]

All input dimensions should have comparable values

Ideally, all features should be in the range [-1,1] or [0,1]

Typical normalisation: mean normalization, feature scaling, coefficient of variation

NLP uses TF-IDF, one-hot encoding, word2vec (already normalised!)
